have a well log and knows very little about the well. No knowledge about seal.

A5. Provisions of the <u>Willamette River</u> Basin rules relative to the development, classification and/or management of ground water hydraulically connected to surface water are, *or* are not, activated by this application. (Not all basin rules contain such provisions.)

Comments: _____ Frazier Creek Ditch is an intermittent stream that has been moved and modified by man. In the area of the proposed development, the stream generally flows during winter rains or storm flows; therefore, this portion of the rule does not apply.

Well(s) # _____, ____, ____, ____, tap(s) an aquifer limited by an administrative restriction. Name of administrative area: ______ A6. Well(s) #____ Comments:

B. GROUND WATER AVAILABILITY CONSIDERATIONS, OAR 690-310-130, 400-010, 410-0070

- B1. **Based upon available data**, I have determined that ground water* for the proposed use:
 - **is** over appropriated, **is not** over appropriated, or **cannot be determined to be** over appropriated during any a. period of the proposed use. * This finding is limited to the ground water portion of the over-appropriation determination as prescribed in OAR 690-310-130;
 - will not or will likely be available in the amounts requested without injury to prior water rights. * This finding b. is limited to the ground water portion of the injury determination as prescribed in OAR 690-310-130;
 - **will not** or **will** likely to be available within the capacity of the ground water resource; or c.
 - **will, if properly conditioned**, avoid injury to existing ground water rights or to the ground water resource: d.
 - i. \square The permit should contain condition #(s) **7B Interference**
 - ii. The permit should be conditioned as indicated in item 2 below.
 - iii. The permit should contain special condition(s) as indicated in item 3 below;

Condition to allow ground water production from no deeper than ft. below land surface; B2. a.

- Condition to allow ground water production from no shallower than ______ ft. below land surface; b.
- **Condition** to allow ground water production only from the c. __ ground water reservoir between approximately______ft. and ______ft. below land surface;
- Well reconstruction is necessary to accomplish one or more of the above conditions. The problems that are likely d. to occur with this use and without reconstructing are cited below. Without reconstruction, I recommend withholding issuance of the permit until evidence of well reconstruction is filed with the Department and approved by the Ground Water Section.

Describe injury -as related to water availability- that is likely to occur without well reconstruction (interference w/ senior water rights, not within the capacity of the resource, etc):

B3. Ground water availability remarks: See conceptual model discussion for more details on geology, ground water and model parameters. Ground water in this area is recharged from precipitation and nearby streams. Stability of the resource should not be a problem.

No well log was filed with the application. I do not know if the applicant checked with the county tax assessor to try and track down a well log based on ownership and date well was constructed. I do not know when the well may have been constructed. Therefore I can not assess whether or not the well was properly constructed when drilled or meets current standards. It is unlikely that the well has a seal that would meet current standards.

C. GROUND WATER/SURFACE WATER CONSIDERATIONS, OAR 690-09-040

C1. **690-09-040** (1): Evaluation of aquifer confinement:

| 1 Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Willamette Aquifer Image: Sands and Gravels - Will | Wel 1 | Aquifer or Proposed Aquifer | Confined | Unconfined |
|--|----------|--|----------|------------|
| | 1 | Sands and Gravels - Willamette Aquifer | | \square |
| | | | | |
| | | | | |
| | 1 | | | |
| | | | | |

Basis for aquifer confinement evaluation: Shallow sands and gravels with shallow water levels - unconfined.

C2. 690-09-040 (2) (3): Evaluation of distance to, and hydraulic connection with, surface water sources. All wells located a horizontal distance less than ¹/₄ mile from a surface water source that produce water from an unconfined aquifer shall be assumed to be hydraulically connected to the surface water source. Include in this table any streams located beyond one mile that are evaluated for PSI.

| Well | SW # | Surface Water Name | GW Elev ft msl | SW Elev ft msl | Distance (ft) | Ċ | Connec | lically cted? ASSUMED | Potentia Subst. Int Assume YES | erfer. |
|------|---------|---------------------|------------------------------------|----------------------|------------------|---|--------|-----------------------------|--|-----------|
| 1 | 1 | Frazier Creek Ditch | 210 - 200 | 205 | 410 | | | | | |
| | 2 | Mountain View Creek | 210 - 200 | 208 | 1400 | | | | | \square |
| | 3 | Ashbar Lake | 210 - 200 | 190 | 4250 | | | | | \square |
| | 4 | Willamette River | 210 - 200 | 180 | 9150 | | | | | |
| | | | | | | | | | | |
| | | | | | | | | | | |

Basis for aquifer hydraulic connection evaluation: <u>Originally, I noted that ground water levels in the area of Frazier</u> Creek Ditch would be below the bottom of the creek in the summer months. Upon further review, it was determined that Frazier Ditch is an intermittent stream within ¼ mile of the well. Intermittent streams in this area only flow as part of the winter or storm runoff; therefore this section of Frazier Ditch is not hydraulically connected to the well. Water Availability Basin the well(s) are located within: WILLAMETTE R > COLUMBIA R - AB PERIWINKLE CR AT GAGE 14174

C3a. 690-09-040 (4): Evaluation of stream impacts for each well that has been determined or assumed to be hydraulically connected and less than 1 mile from a surface water source. Limit evaluation to instream rights and minimum stream flows that are pertinent to that surface water source, and not lower SW sources to which the stream under evaluation is tributary. Compare the requested rate against the 1% of 80% natural flow for the pertinent Water Availability Basin (WAB). If Q is not distributed by well, use full rate for each well. Any checked 🖂 box indicates the well is assumed to have the potential to cause PSI.

| Well | SW # | Well < ¹ / ₄ mile? | Qw > 5 cfs? | Instream Water Right ID | Instream Water Right Q (cfs) | Qw > 1% ISWR? | 80% Natural Flow (cfs) | Qw > 1% of 80% Natural Flow? | Interference @ 30 days (%) | Potential for Subst. Interfer. Assumed? |

comments flow.

C4a. **690-09-040 (5):** Estimated impacts on **hydraulically connected surface water sources greater than one mile** as a percentage of the proposed pumping rate. Limit evaluation to the effects that will occur up to one year after pumping begins. This table encompasses the considerations required by 09-040 (5)(a), (b), (c) and (d), which are not included on this form. Use additional sheets if calculated flows from more than one WAB are required.

Conceptual Model -- Generalized Ground Water Flow Systems. Marc Norton January 8, 2004

Based on:

OWRD GRID - Ground water Resource Information Distribution

OWRD Ground Water Database

Memo on Recommended Vertical Hydraulic Conductivity Values for the Willamette Silt Hydrogeologic Unit When Using the Hunt Analytical Model, Karl Wozniak, January 6, 2004.

Ground-Water Resources of the Willamette Valley, Oregon, 1942, Water-Supply Paper 890, Piper.

Hydrogeologic Framework of the Willamette Lowland Aquifer System, Oregon and Washington, 1998, US Geological Survey Professional Paper 1424 B, Woodward, Gannett, and Vaccaro.

GENERALIZED GEOLOGY

The Willamette Lowland in Oregon and Washington encompasses 3,700 square mile and includes the low-lying parts of the Willamette Valley in Oregon and most of Clark county in Washington. About 70% of the population of Oregon and Clark County reside in the lowlands. The lowland is 145 miles long and averages 10 to 15 miles in width. Water is recharged to the Willamette Lowland aquifer system primarily through the direct infiltration of precipitation on the lowland. The regional water-table map shows an overall pattern of groundwater flow to the major streams, indicating that the base flow of these streams is sustained by ground water discharge. This ground-water discharge fully supports the base flow of streams that head in the lowland and partially support the base flow of the other streams.

HYDROGEOLOGIC UNITS

The aquifer system is composed of five hydrogeologic units, from oldest to youngest:

- 1) the basement confining unit,
- 2) the Columbia River basalt aquifer,
- 3) the Willamette confining unit,
- 4) the Willamette aquifer, and
- 5) the Willamette silt unit.

The basement-confining unit forms the lateral and basal boundary to the Willamette aquifer system. The basement-confining unit includes all the stratigraphic units that underlie either the Columbia River Basalt Group in the northern part of the basin or the basin-fill deposits in the southern part. The unit is composed of marine sedimentary rocks and volcanic rocks of the Coast and Cascade ranges. The basement-confining unit is generally a low yielding aquifer where wells develop water primarily from fractures in the rock. Ground water can be found under unconfined conditions in the highlands and under confined conditions with greater depth and lower elevations. Yields are generally less than 10 gpm and usually decrease over time. The deeper the well, the greater the chance of brackish water being encountered.

The Columbia River basalt aquifer overlies the basement-confining unit and consists of layers of basalt flows of the Columbia River Basalt Group. The thickness of the aquifer generally is several hundred feet but locally is as much as 1000 feet. Ground water in the basalts is generally under confined conditions except in the foot-

hills where they may be unconfined. Well yields vary from tens to hundreds of gallons per minutes. Brackish water has been encountered in several areas, particularly with depth.

The Willamette confining unit consists primarily of fine-grained, distal alluvial fan and low-gradient stream deposits. The fine-grained deposits are considered a regional confining unit because of their wide spread occurrence and low permeability. Ground water in the Willamette confining unit is generally under confined conditions and well yields are very low to "dry".

The Willamette aquifer consists primarily of coarse-grained proximal alluvial-fan and braided-stream deposits. The greatest thickness, and coarsest materials of the Willamette aquifer outside of the Portland Basin occur in six major alluvial fans that were deposited where major streams from the Cascade Range enter the Willamette Lowland. Ground water in the Willamette aquifer unit varies from unconfined to confined conditions, depending on location and depth. Vertical gradients are usually downward except near major streams. Deposits of lower permeable material can act as a confining layer but are generally of limited aerial extent.

The Willamette silt unit is deposited throughout much of the Willamette Lowland by glacial-outburst floods. The deposits range in thickness from 0 to 130 feet. They consist primarily of silt and fine sand of relatively uniform lithology. Ground water in the Willamette silt unit is generally under unconfined conditions and well yields are low, less than 5 to 10 gpm.

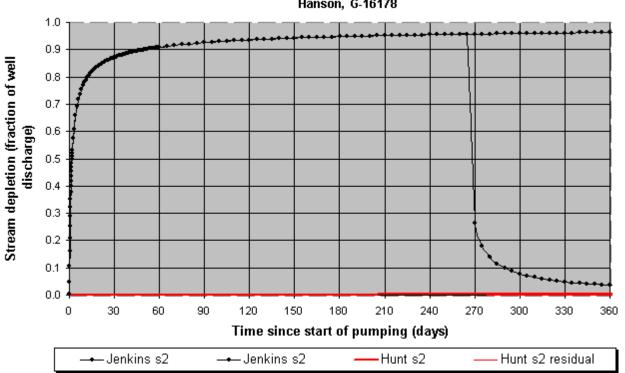

STRUCTURAL BASINS

Outcrops of folded and faulted basalt within the Willamette Valley divide the lowland into four separate areas or structural basins -- from north to south, **the Portland Basin, the Tualatin Basin, the central Willamette Valley, and the southern Willamette valley**. Each of these areas has decidedly different hydrologic and hydrogeologic properties. The aquifer system in each basin, although hydraulically connected through a series of restrictive water gaps, is distinctive.

<u>Tualatin Basin</u>. The Columbia River basalt aquifer and the Willamette confining unit are the only regional hydrogeologic units above the basement-confining unit in the Tualatin Basin. The Columbia River basalt aquifer underlies the entire basin, and its upper surface forms a sediment-filled bowl-like depression.

<u>The Central Willamette Valley</u> All five of the hydrogeologic units occur in the central Willamette Valley. The Columbia River basalt aquifer underlies the entire central Willamette Valley, except for small areas along the far eastern margin. A number of faults have been mapped in the central Willamette Valley, some of which offset the aquifer, and numerous other faults have been mapped in the uplands surrounding the basin where the aquifer crops out. The Willamette aquifer in the central Willamette Valley contains three major alluvial fans -- the Salem fan, the Molalla fan, and the Canby fan. The Willamette Silt unit overlies most of the central valley with a maximum thickness of about 130 feet near the center and thins towards the south and near the margins of the basin.

<u>The Southern Willamette Valley</u> In the southern Willamette Valley, all of the regional hydrogeologic units are present; however, the Columbia River basalt aquifer occurs only in the Stayton area. The Willamette confining unit is thinner in the southern Willamette Valley than elsewhere in the Willamette Lowland. The Willamette aquifer contains the Lebanon fan and the Stayton fan. The Willamette aquifer is much thinner (averaging only about 20 to 40 feet thick) between the alluvial fans of the southern Willamette Valley. The Willamette Silt unit covers most of the southern Willamette Valley and generally thin towards the south.

Transient Stream Depletion (Jenkins, 1970; Hunt, 1999) Hanson, G-16178
